

# The life of the massive stars seen through optical/near-infrared interferometry

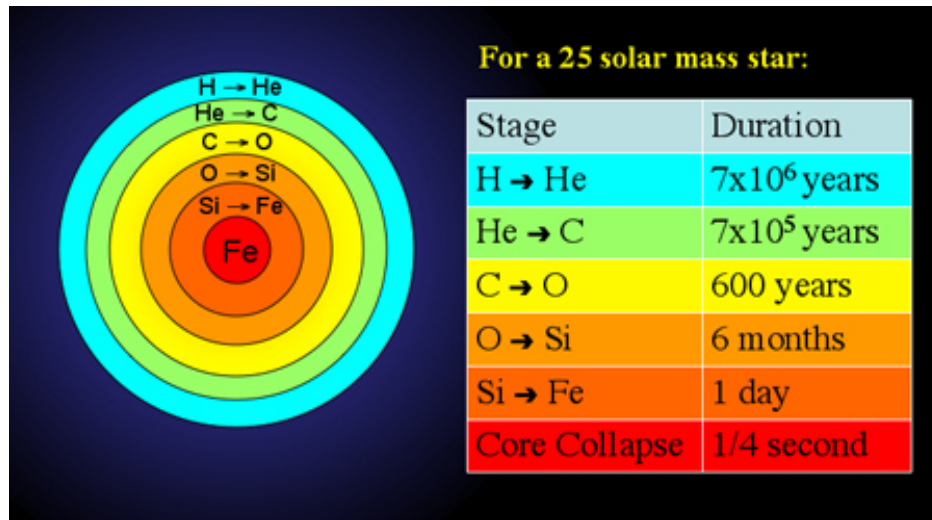

**Joel Sanchez Bermudez (IAA-CSIC), A. Alberdi (IAA-CSIC), R. Schödel (IAA-CSIC)**

**Collaborators: C. Hummel (ESO), J. Maiz Apellaniz (IAA-CSIC), J.-U. Pott (Max-Planck), R. Barbá (Univ. Serena), P. Tuthill (Univ. Sydney)**

# The importance of massive stars

- ▣ Important to the chemical evolution of the galaxies
- ▣ Principal UV-radiation sources
- ▣ Progenitors of the heavier chemical elements
- ▣ Strong stellar-winds and deaths in the form of supernovae

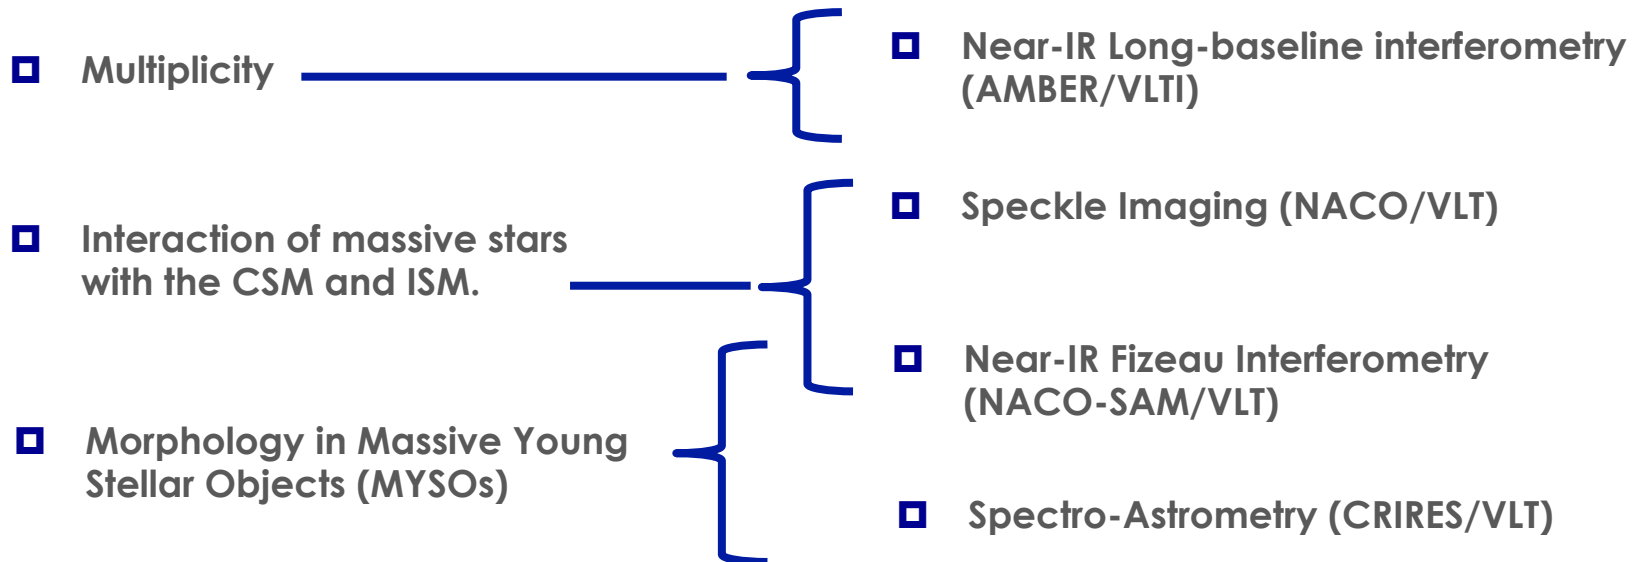

# Massive stars birthplaces

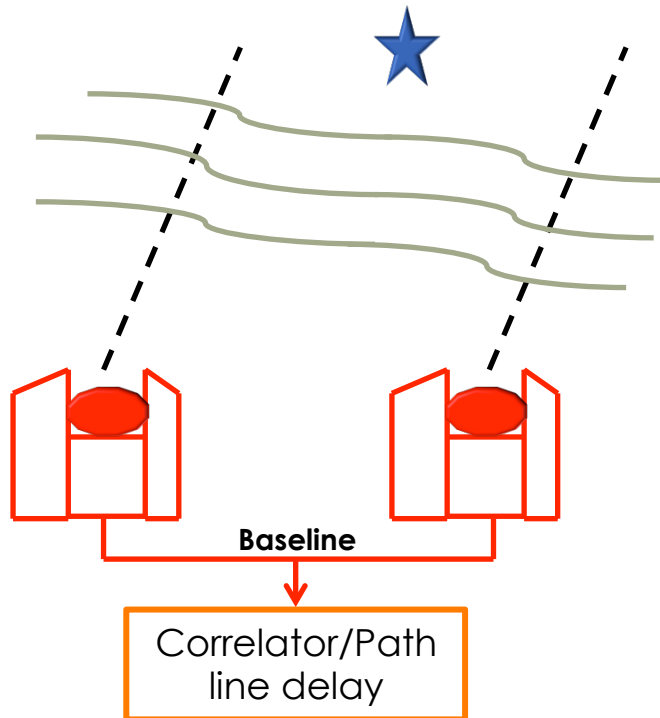

- ❑ Rare (IMF)
- ❑ Born on the main sequence
- ❑ Short life-times ( $\approx$ Ma)
- ❑ Born in very dense clouds

# High angular resolution techniques

# Optical/IR vs Radio Interferometry

- ▣ Visibilities are complex quantities
- ▣ They have **AMPLITUDE** and **PHASE**

- ▣ Optical wavelengths are significantly shorter than radio wavelengths ( $10^4$ - $10^7$ )
- ▣ More important atmospheric effects at infrared wavelengths.
- ▣ The properties of the received radiation are very different between RADIO and OPTICAL/IR wavelengths.

# Optical/IR vs Radio Interferometry

$$D < r_0$$

$$\Theta = \lambda / D$$

$$D > r_0$$

$$\Theta = \lambda / r_0$$

	Radio	Optical/IR
Wavelength	1.3 cm	2.2 $\mu$ m
Coherence time	$\approx$ 10 minutes	20 milliseconds
Fried's parameter	15 km	1 m

# The atmospheric effect

- The atmosphere introduces temporal and spatial anomalies in the wave-front
- **Fried's parameter:** The circular aperture size over which the mean wave-front error is 1 rad<sup>2</sup>.  $r_0 \approx \lambda^{6/5}$ . Large telescopes requires **Adaptive Optics** to achieve diffraction-limited resolution.
- **Coherence time:** Time over which the mean wave-front error changes by 1 rad<sup>2</sup>.  $t_0 \approx \lambda^{6/5}$

	Radio	Optical/IR
Wavelength	1.3 cm	2.2 $\mu$ m
Coherence time	$\approx$ 10 minutes	20 milliseconds
Fried's parameter	15 km	1 m

$$D < r_0$$

$$\Theta = \lambda / D$$

$$D > r_0$$

$$\Theta = \lambda / r_0$$

# The quantum effect

- ▣ **Occupation number** : The average mean energy of a source divided by the energy of a photon

$$\bar{n} = \frac{1}{e^{\frac{h\nu}{kT}} - 1}$$

- ▣ **Radio**: (1cm), T=2.7 K,  $\langle n \rangle \approx 1.4$

(2cm), T=5000 K,  $\langle n \rangle \approx 7000$

- ▣ **Optical**: (0.5  $\mu$  m), T=5000 K,  $\langle n \rangle \approx 0.003$

(2  $\mu$  m), T=1500 K,  $\langle n \rangle \approx 0.008$

- ▣  $n \gg 1$ , rms  $\approx n$

- ▣  $S/N \approx V^2 * N$

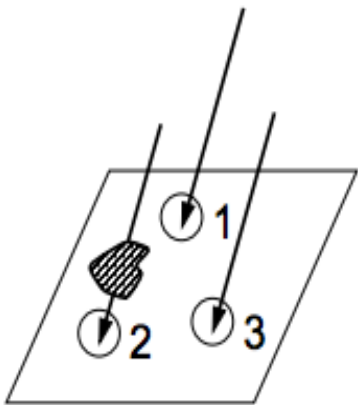

- ▣  $n \ll 1$ , rms  $\approx \sqrt{n}$

- ▣  $S/N \ll 1$

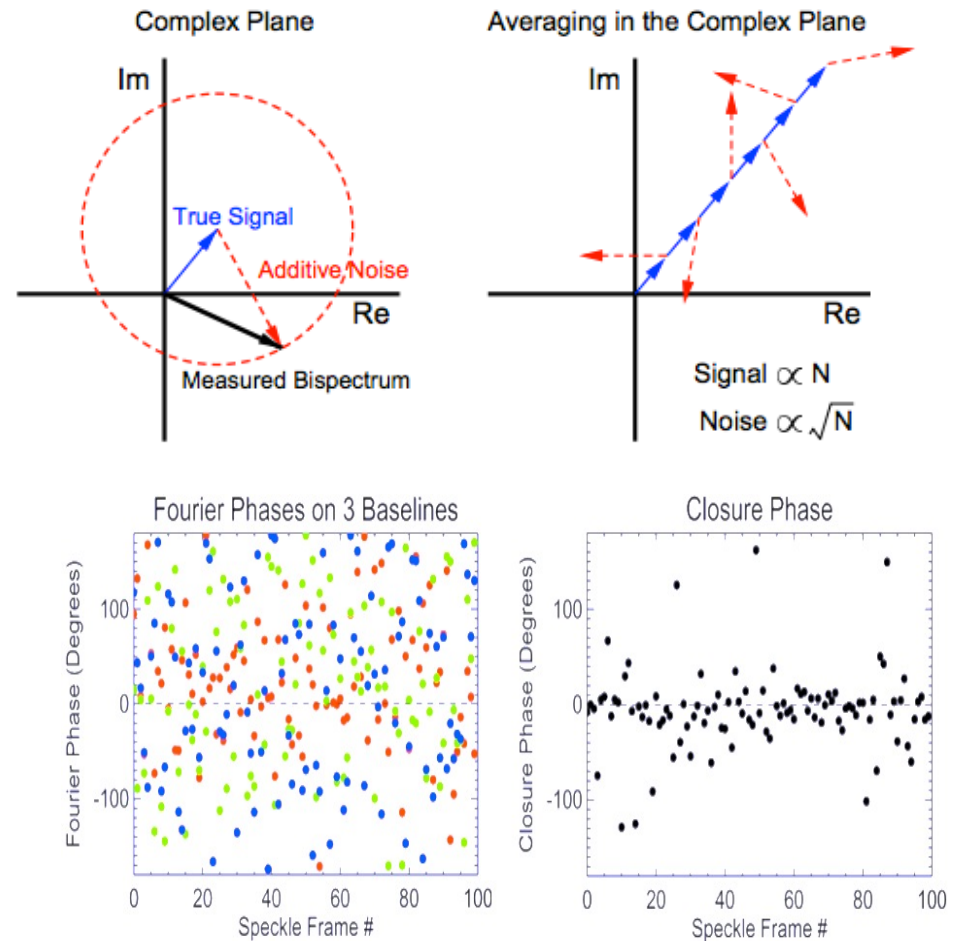

# Interferometric Observables

- In radio interferometry the observables are the **amplitude of the visibility (V)** and the **phase**.
- In optical/IR interferometry we use the **modulus of the visibility (V<sup>2</sup>)** and the **closure phases**.

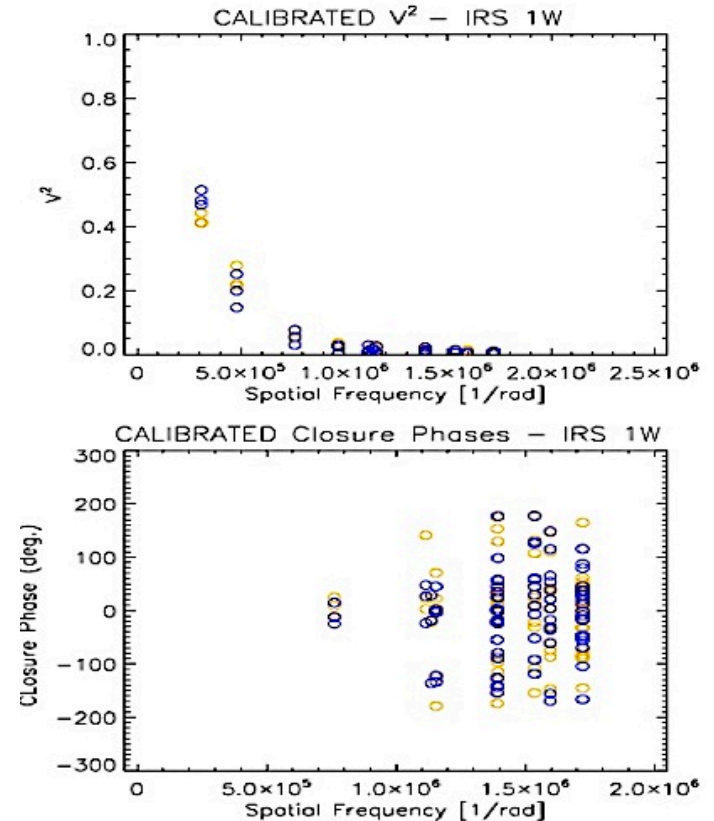

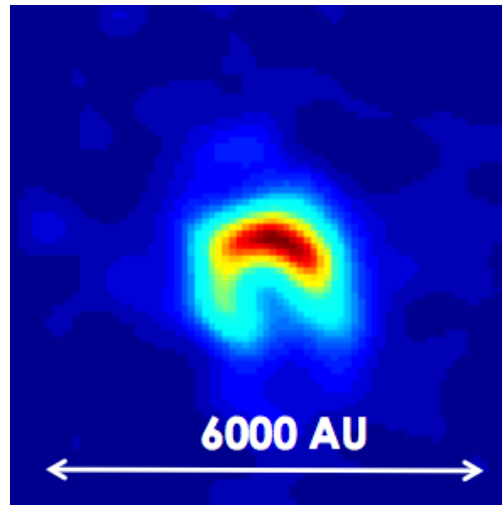

Observed	Intrinsic	Atmosphere
$\Phi(1-2)$	$= \Phi_o(1-2)$	$+ [\phi(2) - \phi(1)]$
$\Phi(2-3)$	$= \Phi_o(2-3)$	$+ [\phi(3) - \phi(2)]$
$\Phi(3-1)$	$= \Phi_o(3-1)$	$+ [\phi(1) - \phi(3)]$

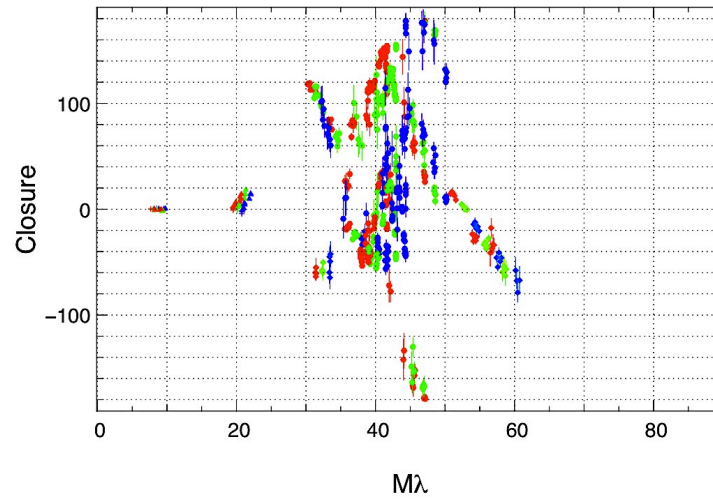

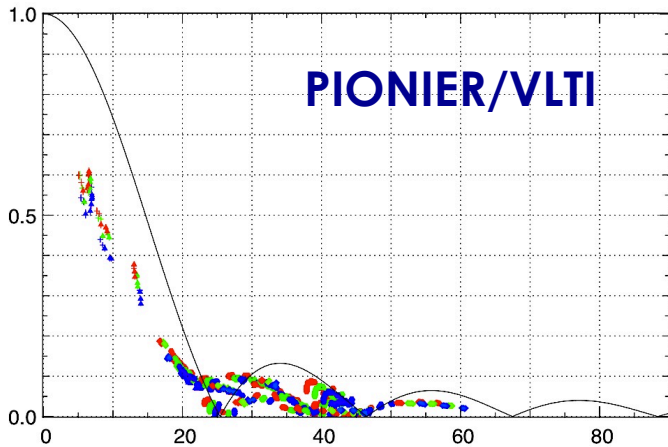

- Closure phases:** Argument of the product of three visibilities produced by a closed triangle of baselines.

# Calibration and Imaging

- Interwoven observations of Calibrator and target are required.
- Calibrators should be point-like sources with similar magnitudes and spectral types as the targets
- Calibrators located at few deg. from targets
- At least three software packages available bases on bispectra maximum entropy methods (BSMEM, MIRA, MACIm)

# Sparse aperture masking interferometry

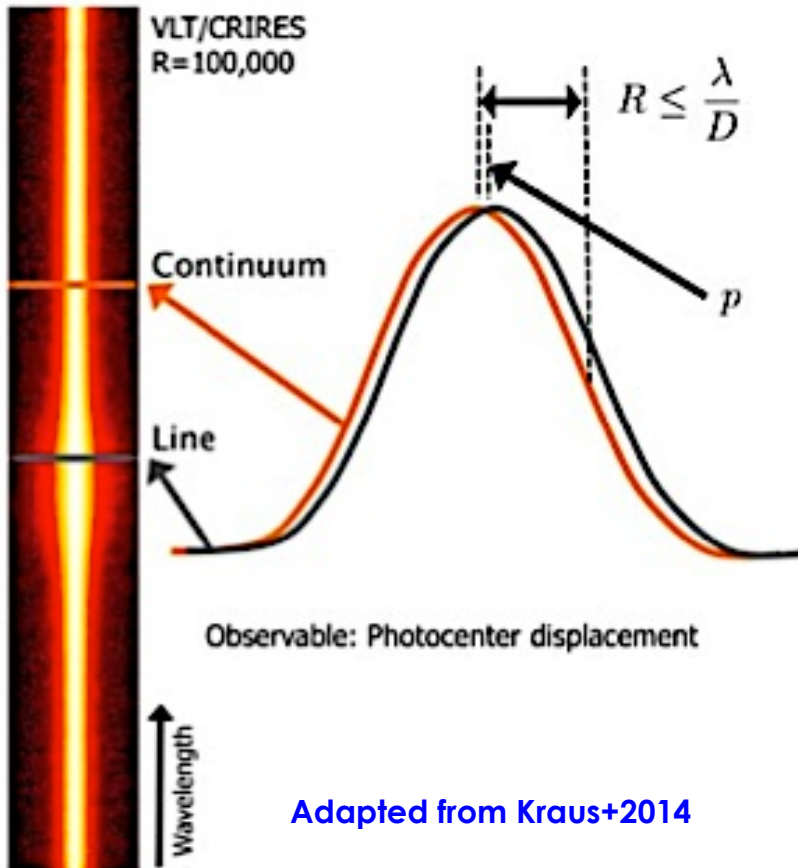

## SAM Interferometry Characteristics:

- Well defined PSF calibration
- SAM cut-off most of the atmospheric noise signal
- The technique is constrained to bright sources
- SAM at VLT is suitable for sources with 4-12 mag
- SAM at VLT offers 4 masks.

$$\theta \approx \frac{\lambda}{2D} \rightarrow \text{Resolution}$$

# Spectroastrometry

# Massive stars at their early stages (NGC3603 IRS9A)

## IRS9A in context:

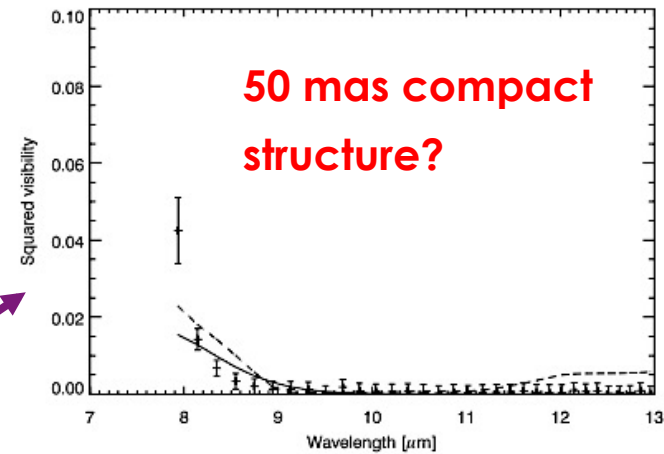

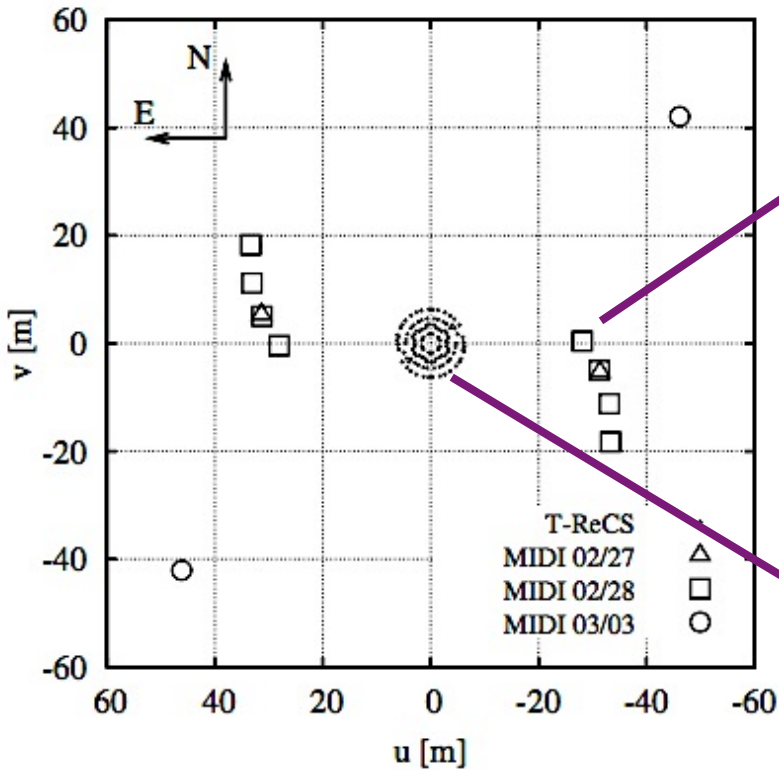

- ▣ Very luminous source ( $2.3 \times 10^5 L_{\odot}$ )
- ▣ Spectral index  $\alpha_{2.2-10\mu\text{m}} = 1.37$
- ▣ Mass: 30-40  $M_{\odot}$
- ▣ Extinction: 4-5 mag

# Mid-infrared interferometric observations of IRS9A

## MID-IR Observations:

- MIDI (9-13  $\mu\text{m}$ )
- T-ReCS (11.7  $\mu\text{m}$ )

# Near-infrared interferometric observations

## NACO setup:

- ▣ 7holes mask (faint object  $\approx 9$  mag)
- ▣ Ks, Lp and M
- ▣ Standard SCI-CAL-SCI sequence
- ▣ Cube mode/pupil tracking
- ▣ NDIT=50seg

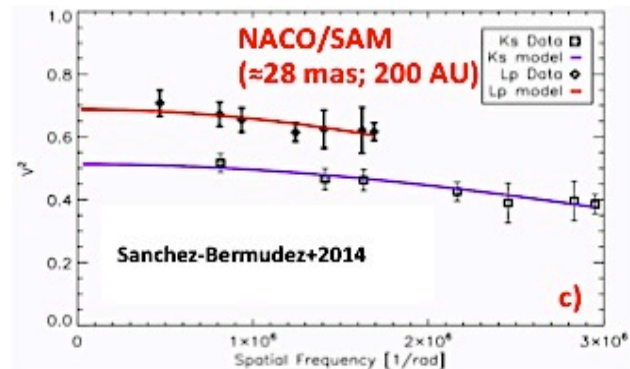

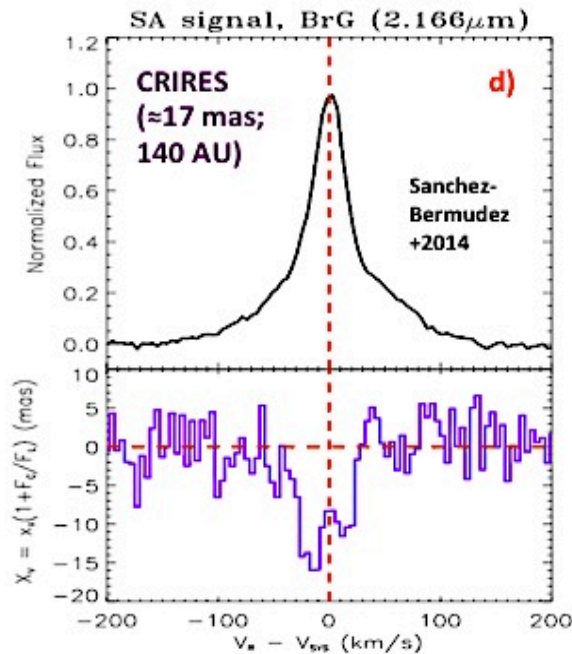

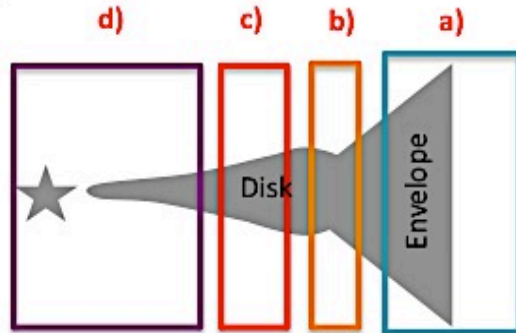

## CRILES setup:

- ▣ H2 ( $2.121 \mu\text{m}$ ) and BrG ( $2.166 \mu\text{m}$ ) emission lines
- ▣  $6''$  slit width;  $R \approx 33000$ ;  $1.5 \text{ km/s}$
- ▣ 3 position angles ( $0^\circ$ ,  $90^\circ$ ,  $128^\circ$ )
- ▣ NDIT=60 seg
- ▣ Ks, Lp and M

# To keep in mind

- Massive stars have strong impact to their surroundings.
- Our understanding of their formation and evolution is still sketchy.
- Observations of massive stars are challenging.
- VLTI has the best angular resolution to study massive stars at near and mid infrared wavelengths.
- Interferometric observations provide us unique information of some of the most important aspect of massive stars (e.g. imaging binaries, circumstellar disks, envelopes).
- The second generation of VLTI instruments will improve imaging capabilities and sensitivity (2-5 mag), opening new opportunities to study more massive stellar systems.
